 Standard heterosis, Okra.

Abstract

Fifty six hybrids obtained from eight parents (ArkaAbhay, ArkaAnamika, DBh-30, DBh-37, DBh-39, DBh-43, DBh-47 and DBh-55) which are crossed in full diallel fashion along with eight parents and four popular hybrids were evaluated for estimating heterosis for yield and yield related traits viz., days to 50 per cent flowering, plant height, number of branches, inter-nodal length, fruit length, fruit diameter, number of fruits per plant, average fruit weight, fruit yield per plant and fruit yield per hectare during rabi season of 2011-2012. The results revealed that the standard heterosis for fruit yield per plant was maximum in the hybrid ArkaAnamika x DBh-43, with a value of 96.97 per cent. This hybrid recorded high standard heterosis for number of fruits per plant, average fruit weight and fruit yield per hectare.

Introduction

Okra (*Abelmoschus esculentus* (L.) Moench), one of the important vegetable crops of India, belongs to family Malvaceae and the genus *Abelmoschus*. It is an economically important vegetable crop grown in tropical and subtropical parts of the world. It is native of tropical Africa. It is called lady's finger in England, gumbo in the United States of America, guino-gombo in Spanish, guibeiro in Portuguese and bhendi in India. It is often cross pollinated crop and thus heterosis can be exploited in it. Heterosis breeding based on the identification of the parents and their cross-combinations is capable of producing the highest level of transgressive segregates (Falconer 1960). It is one of the tools in overcoming yield barrier and increasing productivity. It also identifies the cross combinations which are promising in conventional breeding programme. Heterosis adaptability, biotic and abiotic resistance, general vigour and quality leads to increase in yield, reproductive ability. The initial selection of parents to be involved in any effective hybridization programme depends upon the nature and magnitude of heterobeltiosis (heterosis over better parent) and economic heterosis (heterosis over check) present in genetic stocks. The magnitude of heterosis provides a guide for the choice of desirable parents for developing superior F₁ hybrids, so as to exploit hybrid vigour. It also helps in choosing suitable crosses to be used for commercial exploitation as well as in component breeding programme.

Materials and Methods

Eight parents viz., ArkaAnamika, ArkaAbhay, DBh-30, DBh-37, DBh-39, DBh-43, DBh-47 and DBh-55 selected and were crossed in diallel fashion to analyse the combining ability and heterosis for yield and yield component traits. Fifty six hybrids obtained from full diallel crossing programme, eight parents along with four popular hybrids (Syngenta 152, Mahyco No. 10, Mahyco No. 55, and Mahyco No. 64) were evaluated in three replications of Randomized Block Design during rabi season of 2011-2012. Row-to-row and plant-to-plant distances were maintained at 60 cm and 30 cm, respectively. The crop protection and other cultural practices were carried out as required to raise a good crop.

Observations were recorded on five competitive plants excluding border plants in each replication for days to 50 per cent flowering, plant height, number of branches, inter-nodal length, fruit length, fruit diameter, number of fruits per

plant, fruit weight, fruit yield per plant and fruit yield per hectare. Heterobeltiosis was computed as deviation of mean performance of F_1 from that of better parent (BP). The estimates of economic heterosis were computed as deviation of mean performance of F_1 from that of the commercial hybrids (Syngenta 152, Mahyco No. 10, Mahyco No. 55, and Mahyco No. 64). Magnitude of heterosis and average heterosis was computed according to Turner (1953) and Hayes et al. (1956).

Results and Discussion

The variance due to treatments was found highly significant for all the characters studied. The parents and hybrids exhibited highly significant variation for all the characters studied. It indicates significant difference among parents and hybrids. Parents vs hybrids exhibited significant variation for days to 50% flowering, plant height, number of branches days, inter-nodal length, number of fruits, fruit weight, average fruit yield per plant and yield per hectare and non-significant variation for fruit length and fruit diameter. Variance due to F_1 's and reciprocal was found significant for all characters studied. Variance due to F_1 's v/s reciprocal interaction was highly significant for days to 50% flowering, number of branches per plant, inter-nodal length, number of fruits, average fruit yield per plant and non-significant for plant height, fruit length, fruit diameter, fruit weight and fruit yield per hectare (Table 1).

The range of heterosis for the trait fruit yield per plant was -20.78 to 96.46 percent over mid parent, -35.22 to 89.13 over better parent and -29.82 to 78.25 over commercial hybrid, -9.15 to 6.08 percent and -3.37 to 6.08 per cent for days to 50 percent flowering, -5.56 to 4.63, -7.48 to 4.26 and 1.49 to 12.69 for days to 50 percent flowering, -29.69 to 56.46, -40.37 to 35.77 and -15.56 to 85.02 for plant height, -30.00 to 73.33, -36.36 to 62.50 and -33.33 to 44.44 for number of branches per plant, -15.69 to 44.56, -27.12 to 37.21 and 27.72 to 103.96 for inter-nodal length, -5.24 to 11.50, -11.00 to 6.97 and -6.94 to 12.75 for fruit length, -8.10 to 10.28, -11.67 to 9.43 and -7.27 to -7.27 for fruit diameter, -14.67 to 56.36, -30.43 to 48.28 and -23.81 to 47.62 for average fruit weight and -12.41 to 96.96, -24.42 to 89.10 and -15.6 to 86.68 for fruit yield per hectare respectively (Table 2).

The standard heterosis for days to 50 % flowering over Mahyco 64 ranged from 2.47 per cent (ArkaAnamika x DBh-55) to 16.67 per cent (DBh-43 x DBh-39) and none of hybrids exhibited significant negative heterosis. The negative average heterosis (-2.87%) also substantiated the fact that the hybrids in general were early in flowering. Swamy Rao (1997), Shukla and Gautam (1990), Bendaleet al. (2003), Dahakeet al. (2006), Amutha et al. (2007) and Weerasekara et al. (2008) also reported heterosis for earliness in okra hybrids. In case of plant height, 38 hybrids exhibited significant standard heterosis and an average heterosis of 13.74 per cent was observed for this character over the parents inferring that hybrids were taller than their parents. The predominance of tallness over dwarfness, indicated tallness as a dominant character as reported by Singh et al., (1975), Vijay and Manohar, (1986), Wankhadeet al., (1997), Dhankaret al., (1996), Dhankar and Dhankar, (2002), Dahakeet al., (2006), Amuthaet al., (2007), Sriramet al., (2007) and Weerasekara et.al, (2008). Four hybrids showed highly significant heterosis and an average heterosis was 9.66 per cent for number of branches per plant indicating that hybrids had more branches than their respective parents. 5 hybrids over mid-parent, 8 over better parent had expressed negative heterosis for intermodal length. Negative heterosis is desirable for the character inter-nodal length. But, only few crosses recorded negative heterosis over mid parent, better parent and none of the hybrids exploited negative heterosis over standard checks. The average heterosis for the character was 15.48 per cent which indicates that hybrids had longer inter-nodal length than the parents.
