Abstract

By revisiting free particle \( v(x)=0 \) endowed with position dependent mass \( m(x) = \frac{1}{(1+|xx|^2)^2} \) has \( d=1 \) (the inter-dimensional). Starting with the kinetic energy operator, we will try to solve the equation by simplification mathematical method to find energy spectrum, then get stander form for the energy whose dependent on the ordering ambiguity.

Introduction:-

Position dependent mass quantum particles in non-relativistic quantum theory have inspired researchers in the last few years [1-4]. They found new useful and interesting models help them in physical obstructions [5], semiconductors [6], quantum dot [7], quantum liquids [8], He-clusters [9] and metal clusters [10]. Quantum mechanical particle endowed with PDM erupt in the system of quantum mechanics to solve more problems of a delicate nature like example: the \( m(x) \), kinetic energy and the momentum operator does not commute [11].

In other side, they try to find a solution for the Schrödinger equation in \( d \)-dimensional by dependent a canonical transformation (PCT) method [12,13] under task change variables [14-16]. The eigenvalues and eigenfunctions are mapped for the exact solutions for Schrödinger equation [17-19].

Recently, PCT for PDM–quantum particle introduced in \( d \)-dimensional [1]. The inter-one degeneracies associated with the isomorphism between angular momentum \( l \) and dimensionality \( d \) builds up the ladder of excited states for any given values e.g. nonzero \( l \) and the radial quantum number \( n_r \). By choosing the parameters \( \alpha = \gamma \) and \( \beta = -1 \) with the PCT method, it lead to get the Schrödinger equation with the effective potential (Poschl-Teller potential) [20].

Here, we choose a free particle with \( v(x) = 0 \), the inter – dimensional \( d = 1 \) and keeping on the von-Roos ordering in the general form \( \alpha + \beta + \gamma = -1 \), we will try to find a new formula for energy spectrum depend on position dependent mass parameters.

Time–independent Schrödinger equation in one- dimensional by PCT method:-
The stander form time-independent Schrödinger equation is given:

\[
-\frac{\hbar^2}{2m} \frac{\partial^2}{\partial x^2} \psi(x) + v(x)\psi(x) = E\psi(x)
\]  

(1)
In which \( v(x) \) is a real potential and \( E \) is the energy of the particle.

Further, kinetic energy of quantum particle with position-dependent mass in one dimension is given by [1]
\[
T = \frac{1}{4} \left( m^a pm^b pm^c + m^d pm^e pm^f \right)
\]  
(2)

In which \( \alpha + \beta + \gamma = -1 \) with \( p = -i\hbar \frac{d}{dx} \) and \( m = m(x) \).

Using equation (1) the time-independent Schrödinger equation for a position-dependent mass particle reads:
\[
\frac{1}{4} \left( m^a pm^b pm^c + m^d pm^e pm^f \right) \psi(x) + v(x)\psi(x) = E\psi(x)
\]  
(3)

Bysimplifying Eq.(3) one can obtain:
\[
\frac{-\hbar^2}{4} \left[ \frac{2}{m} \psi'' + (-2) \frac{m^2}{m^2} \psi + \frac{m^2}{m} \left( \beta(\gamma + \alpha) + \gamma(\gamma - 1) + \alpha(\alpha - 1) \right) \psi + \left( \frac{1 - \beta}{m^2} \right) m^\prime \psi \right] + v\psi = E\psi
\]  
(4)

Where a prime mean derivative with respect to its argument.

Using point canonical transformation (PCT) by introducing \( \psi(x) = g(x)\varphi(q(x)) \) and the latter equation reads:

\[
\frac{-\hbar^2}{4} \left[ \frac{2}{m} \left( g''(x)\varphi(q(x)) + 2g'(x)q\varphi'(q(x)) + g(x)q^2\varphi''(q(x)) \right) + (-2) \frac{m^\prime}{m^2} \right] \]
\[
\left( g'(x)\varphi(q(x)) + g(x)q\varphi'(q(x)) \right) + \frac{m^2}{m^2} \left( \beta(\gamma + \alpha) + \gamma(\gamma - 1) + \alpha(\alpha - 1) \right) g(x)\varphi(q(x))
\]
\[
+ \frac{1 - \beta}{m^2} m^\prime g(x)\varphi(q(x))
\]
\[
+ V(q(x))g(x)\varphi(q(x)) = Eg(x)\varphi(q(x))
\]

(5)

To have a Schrödinger equation, we set \( \varphi'(q(x)) \) to be zero, therefore \( g^2(x)q'(x) = m(x) \).

After that, we set the coefficient of \( \varphi''(q(x)) \) to be constant, so \( q^2(x) = m(x) \).

\[
\frac{-\hbar^2}{4} \left[ \frac{-3}{16} m(x)^{-\frac{7}{2}} m^2 + \frac{1}{4} m(x)^{-\frac{3}{2}} m^\prime \varphi(q(x)) + m(x)^{\frac{1}{2}} q^2 \varphi'(q(x)) + (-2) \frac{m'}{m^2} \right]
\]
\[
\left( \frac{m}{m^2} \right) \left( \frac{m}{m^2} \right)^2 \left( \beta(\gamma + \alpha) + \gamma(\gamma - 1) + \alpha(\alpha - 1) \right) \varphi(q(x))
\]
\[
+ \frac{1 - \beta}{m^2} m^\prime m(x)^{\frac{1}{2}} \varphi(q(x))
\]
\[
+ V(q(x))m(x)^{\frac{1}{2}} \varphi(q(x)) = Em(x)^{\frac{1}{2}} \varphi(q(x))
\]

(6)

Dividing Eq.(6) by \( m(x)^{\frac{1}{2}} \) yields:
\[
\frac{-\hbar^2}{4} \left[ \frac{2}{m} \left( \frac{-3}{16} m^2 + \frac{1}{4} m(x)^{-\frac{3}{2}} m^\prime \varphi(q(x)) + m(x)^{\frac{1}{2}} q^2 \varphi'(q(x)) \right) - \frac{1}{2} \frac{m^2}{m^2} \right] \varphi(q(x)) + V(q(x))\varphi(q(x)) = E\varphi(q(x))
\]  
(7)

Hence, we obtain Schrödinger equation that reads:
\[
\left( -\frac{1}{2} \frac{d^2}{d\varphi} + V_{eff} \right) \varphi(q(x)) = \frac{E}{\hbar^2} \varphi(q(x))
\]  
(8)

With the effective potential for free particle \( V(q(x)) = 0; \)

\[
913
\]
\[ V_{\text{eff}} = \frac{7}{32} m^2 - \left( \frac{1}{8} - \frac{(1 - \beta)}{4} \right) m^2 - \frac{1}{4} m^2 \left( \beta (y + \alpha) + \gamma (y - 1) + \alpha (\alpha - 1) \right) \]

(9)

**Introducing example of vanishing mass with Schrödinger equation:-**

The form of mass that is used here:

\[ m(x) = \frac{1}{(1 + (kx)^2)^2} \quad ; \quad k: \text{is a constant} \]  

(10)

Which in turn gets:

\[ q(x) = \int_0^x \frac{dx}{(1 + (kx)^2)^2} \Rightarrow q(x) = \frac{1}{k} \tan^{-1}(kx) \]

(11)

Also one finds, from the latter equation:

\[ \tan(kq(x)) = kx \]

(12)

By considering these results into the equation (10), one finds:

\[ m(x) = \cos^4(kq) \]

(13)

\[ m'(x) = -4k\cos^3(kq) \sin(kq) q'(x) \]

(14)

\[ m''(x) = -4k(-3k\cos^2(kq) \sin^2(kq) q^2 + k\cos^4(kq) q^2 + \cos^3(kq) \sin(kq) q') \]

(15)

Then the effective potential will give as:

\[ V_{\text{eff}} = k^2 \tan^2(kq) + \frac{k^2}{2} - (1 - \beta) \left( k^2 \left( 5 \tan^2(kq) - 1 \right) - 4 \left( \frac{\beta (y + \alpha)}{y (y - 1) + \alpha (\alpha - 1)} \right) \tan^2(kq) \right) \]

(16)

\[ V_{\text{eff}} = -\frac{k^2}{2} - k^2 \beta + (\lambda (\lambda - 1)k^2 \tan^2(kq)) \]

(17)

Where \((\lambda (\lambda - 1) = 6k^2 + k^2 \beta - 4(\beta (y + \alpha) + \gamma (y - 1) + \alpha (\alpha - 1))\)

So Schrödinger equation will be as follows:

\[ \left( -\frac{1}{2} \frac{d^2}{d q^2} + \frac{(\lambda (\lambda - 1)k^2)}{\cos^2(kq)} \right) \varphi(q(x)) = \epsilon \varphi(q(x)) \]

(18)

here \(\epsilon = \frac{E}{k^2} + \frac{k^2}{k^2} + k^2 \beta \).

Now we will solve the equation (18) by change the variable, by considering a new function which is \( \varphi(z) = \cos^4(kq) F(z) \) where \( z = \sin^2(kq) \) that is lead to \( z = (1 - z)^2(kq) F(z) \).

Hence we find our equation in hypergeometric form:

\[ z(1 - z)F'' + \frac{1}{4}(2 - 4(1 + \lambda)z)F' + \frac{2\epsilon - \lambda^2 k^2}{4k^2} - F = 0 \]

(19)

By comparing Eq. (19) with the solution of the second order hypergeometric equation – which in the form \((x(1 - x)F'' + (c - (a + b + 1)x)F' + abF = 0)\) – that it yields:
\[ b_r = \frac{\lambda \pm \sqrt{\lambda^2 - 4\left(\frac{\epsilon^2}{4} - \frac{\epsilon}{2k^2}\right)}}{2} \]

So that :
\[ a = \frac{\lambda - \frac{2\epsilon}{k^2}}{2} \text{and } b = \frac{\lambda + \frac{2\epsilon}{k^2}}{2} \]
\[ \frac{1}{2} \left( \lambda - \frac{2\epsilon}{k^2} \right) = -a \quad ; (a) \text{ is an integer number.} \]

And \( \varepsilon_n = 2k^2(a + \frac{\lambda}{2})^2 \).

Now trying to get the energy by using the solution of the second independent Hypergeometric equation which it is read:
\[ F(x) = c_1 F(a, b; c; x) + c_2 x^{1-c} F(a + 1 - c, b + 1 - c, 2 - c; x) \]  \hspace{1cm} (20)

Using equation above, one can obtain:
\[ E_n = 2k^2(a + \frac{\lambda}{2})^2 - \frac{k^2}{2} - k^2 \beta \]  \hspace{1cm} (21)

The last Eq.(21) represent to the total energy.

**Conclusion:**

In this work we have considered the one dimensional quantum particle with vanishing position-dependent mass and \( v(x) = 0 \). Our main concern here to introduce the general form of the Schrödinger equation with the ordering ambiguity in its standard form \( a + b = -1 \). In other word, the energy spectrum depends on the parameters of position dependent mass \( a, b, \text{and } c \). One can see the larger part of energy depend on the ordering ambiguity. Add to this the effect potential (Poschl-Teller potential) here has a new option with the von-Roos ordering. The exact solution mapped to match the attendant setting of our free particle with the position-dependent mass \( (m(x) = 1(1+(kx)^2)^2) \).
