#### Abstract

Population rise coupled with urbanization and industrialization has resulted in over exploitation of ground water resources and lowering of the water table in many areas. The availability of clean water is at stake when the modern agricultural activities demands more water for irrigational activities. Various treatment systems which are a combination of physical, chemical or biological processes are used for purification and recycling of water. But these are expensive and unaffordable to common man. Bioremediation is an excellent, low cost option to ward off the pollutants. It has been successfully used in constructed wetlands, an ecosystem with the assemblage of plants, microbes and the abiotic factors. The paper analyses the ability of Azolla to remove nutrients from secondary treated sewage water which if released directly to water bodies result in eutrophication. The present study analyses the nutrient removal capacity of Azolla from waste water and shows that the growth of Azolla remove 54.8 per cent ammonia, 50 percent total organic carbon, 33.3 percent organic matter, 71.4 per cent nitrite, 68.65 per cent available phosphorous and 80.52 per cent total phosphorous from wastewater and prevents the eutrophication in water bodies.

#### Introduction:-

Increased industrialization, urbanization and rapid population explosion has given way to increased environmental pollution (CPCB, 2008; Arora et.al. 2009; Sood et al., 2011; Sachdeva and Sharma, 2012). The pollutants in the form of organics from herbicides, insecticides and inorganics like trace elements, heavy metals and metalloids are being discharged into different compartments of earth- soil, water and air. Pollutants are getting added with irrigation water rendering the agricultural soil unproductive by turning them saline. In modern agriculture there is a need for intensive irrigation. This has resulted in over exploitation of ground water resources and lowering of the water table turning many areas drought affected. The world will eventually face a war like situation for water and the disputes between different states for water sharing is already in the anvil. The 3R principle of Reduce, Recycle and Reuse is the solution to the problem of water scarcity and maintaining sustainability in water usage and it becomes mandatory to recycle wastewater. Conventional wastewater treatment processes includes physical, chemical and biological methods which are commonly expensive. Hence, cost effective and efficient method of wastewater treatment through the use of constructed wetland has gained its importance.

India which was once a treasure house of wetland, the natural water purifiers and one among the richest holders of biodiversity is tremendously being affected by the agricultural development and land use changes (Bassi et al., 2014). Decline in the natural wetland which are capable of assimilating the pollutants with their self-regulating nature, has led to design and construction of artificial wetlands. The use of constructed wetlands for treating wastewater has gained its importance since 1950 (Vymazal, 2010) and is increasingly used due to its low cost and effectiveness. These are engineered ecosystems with an assemblage of plants, animals and microbes interacting to improve the quality of point and non-point sources of pollutants and are found to be effective in treating organic pollutants which remain even after the secondary treatment of wastewater in treatment tanks. These artificial wetlands are capable of providing various ecosystem services which are the benefits that humans obtain from nature. This involves bioremediation, water quality improvement, flood storage, nutrient cycling, habitat for fish and other organisms, and the intangible benefit of recreation and aesthetic function.

#### **Bioremediation as an ecosystem function:-**

Bioremediation is one of the most important ecosystem functions for a wetland (MA, 2005) and a restorative function in constructed wetlands. Bioremediation is the use of biological intervention for mitigating the toxic effects caused by the pollutants (Prasad and Singh, 2011) and is one of the most innovative and cost effective method used in wastewater treatment. The bioremediation activities carried out by the constructed wetlands name them as a green alternative to conventional technologies (Ranalli and Lundholm, 2008) and its use in wastewater treatment has been widely discussed. Macrophyte utilization for wastewater nutrient removal had been reported and discussed frequently (Fisher, 1988, DeBusk et al, 1989; Oron, 1990). Macrophyte being commonly used are water hyacinth, parrot feather, duck weed, reed, *Azolla*. *Azolla*, a freely floating aquatic macrophyte is a promising fern capable of carrying out bioremediation activities (Singh, 1977, 1989; Watanabe, 1982; Arora and Saxena, 2005; Arora and Singh, 2003; Sood et al, 2012; Pandey et al., 2015; Noorjahan and Jamuna, 2015; Kollah et al., 2016) and is widely used for treating municipal sewage water.

#### **Importance of *Azolla* in Bioremediation:-**

The genus *Azolla* was established by Lamarck in 1783. The name *Azolla* is derived from two Greek words 'azo' means to dry and 'alloyo' means to kill (Jaeger, 1978). It has several advantages, the most important being the ability to grow in least time, due to which it is referred to as 'super plant' (Wagner, 1997). The presence of symbiotic nitrogen-fixing cyanobacteria, *Anabaena azollae*, within its leaf cavities furnishes the plant with its requirement for nitrogen. In exchange, the fern provides the endosymbiont with a protected environment and supplies it with a carbon source in the form of sucrose (Peters & Meeks, 1989). The nitrogen sequestering potential of the organism makes it play a major role in agriculture by increased rice productivity due to application as a dual crop and a bio fertilizer (Singh et al, 1981). *Azolla* biomass can be used as bio-fertilizer or as a feed supplement for aquatic and terrestrial animals due to its protein; crude fiber and mineral content (Lumpkin and Plunknet, 1980). Moreover, the growth of *Azolla* in natural water bodies forms a mat which can help reduce the evaporation of water from them thereby making water available year round. In this century, where global warming and increased greenhouse gas (GHG) emission is taking place at a fast pace, *Azolla* can be successful in mitigating carbon dioxide which is a major greenhouse gas with high global warming potential. The study by Speelman et al, 2009 has given evidence on the ability of *Azolla* to reduce the global temperature by carbon sequestration. The study also highlighted the presence of *Azolla* in the Eocene period when there was a shift from the green house to ice age due to the uptake of carbon dioxide by the plant. Studies have also revealed that the plant has the ability to reduce methane (another prominent GHG) emission from paddy fields due to the thick layer formed over the surface of water (Mujiyo et al, 2016).

The present work emphasizes the efficiency of *Azolla* to remove nitrogen, phosphorous and carbon from secondary treated municipal effluent for use in constructed wetlands. *Azolla* among other commonly used ferns (duckweed, pennywort, cattail, bulrush, water hyacinth) is better suited for removal of nutrients from wastewater. This is because; the average ratio of N to P in most plant is 10:1. In most of the cases of using the common marophytic plants, phosphorous will remain even after nitrogen removal. *Azolla* is different as it possesses N<sub>2</sub> fixing capacity hence it removes, phosphorous even after nitrogen has been consumed. Therefore, more efficient removal of phosphorous can be sought. In addition, they have a rapid doubling time and can be grown in aquatic media as long as favorable temperature exists.

In this backdrop, the objectives of the paper are:

1. To analyze the growth characteristics of *Azolla* in different medium-tap water, primary and secondary treated wastewater,

2. To analyze the physico-chemical parameters associated with the growth of *Azolla*

### Methodology:-

*Azolla microphylla* fronds were cultured in Espinase and Watanabe (E and W) medium in 20\*25\*5cm plastic trays in polyhouse to produce healthy biomass. The biomass produced were harvested, washed with distilled water and gently blot dried to remove excess moisture and used as inoculant for further experiments. Partially treated municipal effluent (primary and secondary) were obtained from Nilothi sewage treatment plant, New Delhi. Fresh *Azolla* fronds (10g) were grown in trays for seven days. Tap water, E and W medium, primary and secondary treated municipal water (in triplicates) served as growth medium. Experiments were conducted with uninoculated primary and secondary treated water which served as controls, to check the natural attenuation (due to the presence of natural micro flora in water). After seven days *Azolla* was harvested and blot dried and final weight, doubling time and RGR were calculated. The biomass harvested were dried in oven at 60°C till constant weights were obtained. Known amount of dry biomass from each replication was digested with triacid ( $\text{HNO}_3 + \text{HClO}_4 + \text{H}_2\text{SO}_4$  in ratio 9:2:1) mixture on a hot plate till a clear solution was obtained and suitably diluted with distilled water. Percentage of phosphorous in dry *Azolla* was calculated.

The growth characteristics of *Azolla* was studied by inoculating in primary and secondary treated sewage effluents. These were compared with the growth obtained in medium and tap water. Initial and final levels of nutrients like total and available phosphorous (P), Total Organic Carbon (TOC), nitrite and ammonia were analyzed following American Public Health Association standard (APHA, 1999) methods for water and wastewater. Accordingly total and available P was analysed by ascorbic acid method, TOC by Wakley and Black method, ammonia by nesslerization method and nitrite by colorimetric method. Physical parameters including color and pH were noted.

### Doubling time:-

Doubling time is expressed as the number of days that are required for the biomass of the plants to double. Doubling time was calculated using the formula developed by Subudhi and Watanabe, 1981.

$$\text{Double time (DT)} = t/r$$

Where, t-Experiment period,

$$r = \log (W_1/W_0) \cdot 0.301$$

Where,

$$\begin{aligned} W_1 &= \text{Weight of } Azolla \text{ after 't' days} \\ W_0 &= \text{Weight of initial inoculum} \\ 0.301 &= \text{factor} \end{aligned}$$

### Growth Rate:-

Growth rate of *Azolla* is expressed in terms of a daily relative growth rate (RGR). This is defined as the daily increment in total biomass. The relative growth rate is calculated using the formula (Subudhi and Watanabe, 1981)

$$\text{RGR/g/day} = \frac{0.693}{\text{Doubling time}}$$

Where, 0.693 is a factor

### Results and Discussion:-

The color of primary treated wastewater was observed to change from brown to colorless after treatment with *Azolla*. The pH was found to be 8-9 which had increased slightly after growth of *Azolla*.

#### Objective 1:-Growth Characteristics of *Azolla microphylla* on different media

The temperature dependence of the *Azolla* species on the growth was analyzed by growing the *Azolla* samples in three different temperatures to find out the optimum temperature for the growth of *Azolla* sps. The comparison was made between three temperature ranges.

When the temperature was 10-20°C, the maximum relative growth rate and minimum doubling time was shown by the medium (0.15 & 4.57 respectively) followed by tap water (0.14 & 4.93 resp.). The secondary treated wastewater had shown a lower doubling time compared to primary treated wastewater. This may be due to the presence of

reduced level of ammonia in secondary treated wastewater. The percentage P was found to be highest in *Azolla* grown in medium followed by tap water and secondary treated water.

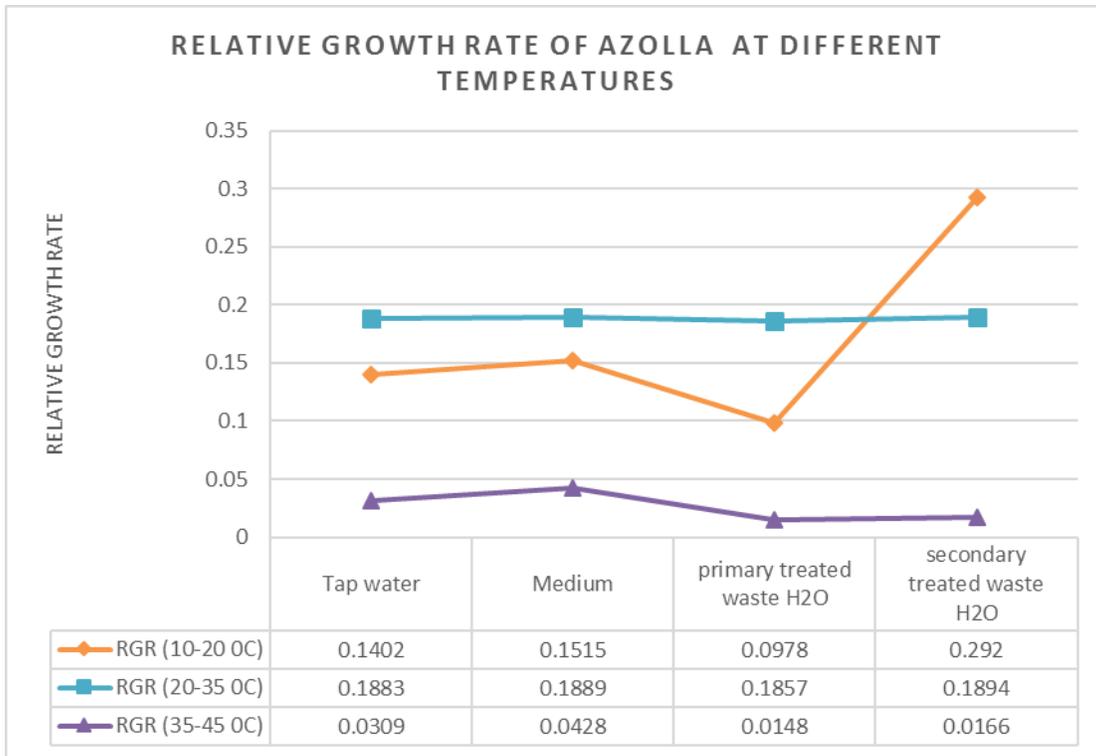

Maximum relative growth rate and minimum doubling time among the samples were observed in when temp was around 20-35°C. A least doubling time of 3.66 days was shown by *Azolla* grown in secondary treated effluent. This was comparable to Relative Growth Rate (RGR) of medium and tap water (3.67days and 3.68 days). The highest RGR was shown by *Azolla* grown in primary treated wastewater. Thus the secondary treated wastewater supported better growth than standard media and tap water. The highest percentage P was found in tap water followed by secondary treated wastewater (0.28 and 0.27 resp.).

When the temperature ranged from 35-45°C, the temperature was unfavorable for the growth of *Azolla*. The doubling time was found to be too high for all the four effluents. However, the growth rate of *Azolla* was found to be comparatively more in secondary treated wastewater compared to primary treated effluents. Due to the reduced growth of *Azolla* there was also growth of green algae in 1<sup>0</sup> and 2<sup>0</sup> treated effluents. This has further inhibited the growth of *Azolla*. The *Azolla* samples were also dried in oven and percentage P was calculated from the dry weight. The percentage P was higher in primary treated water followed by secondary (0.48 and 0.44 resp.). This higher value shown was due to presence of green algae along with *Azolla*.

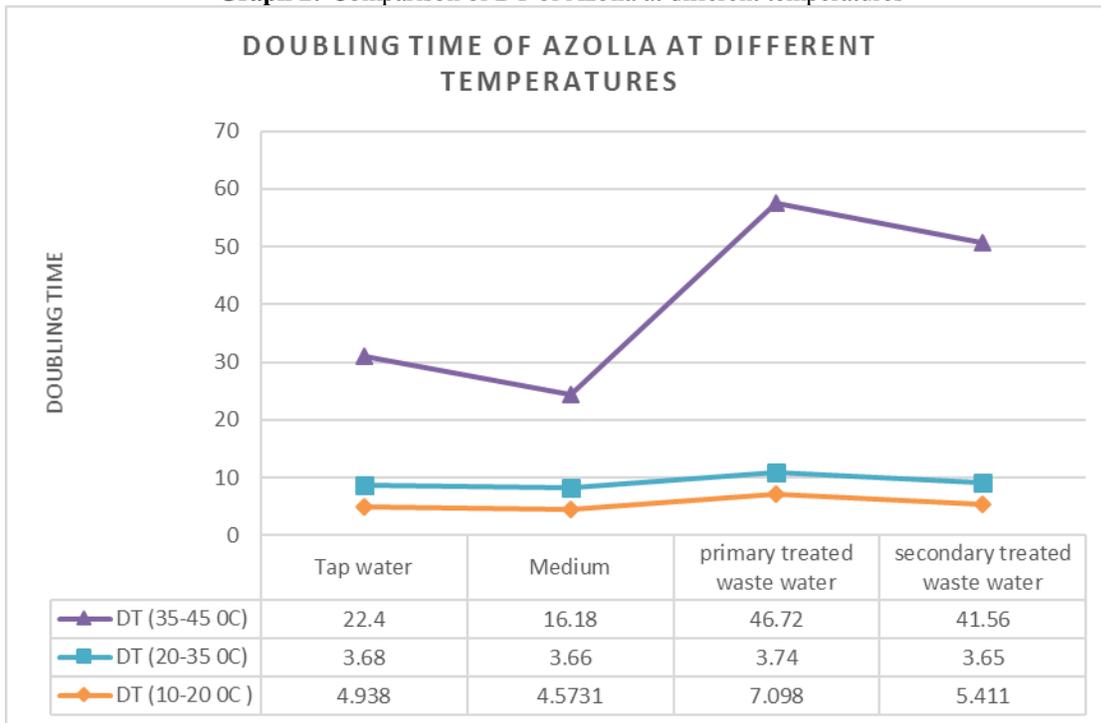

**Table 1:**-Growth characteristics of *Azolla* in different media

Sample 1						
Temp: 10-20 °C						
	Initial wt.	Final wt. (g)	DT	RGR	Dry wt. (g)	% P in dry wt.
Tap water	10	26.716	4.938	0.1402	1.200	0.21
Medium	10	28.89	4.5731	0.1515	1.313	0.23
1 <sup>0</sup> treated waste H <sub>2</sub> O	10	19.85	7.098	0.0978	1.023	0.15
2 <sup>0</sup> treated waste H <sub>2</sub> O	10	24.79	5.411	0.2920	1.286	0.16
Sample 2						
Temp: 20-35 °C						
Tap water	10	54.77	3.68	0.1883	1.87	0.28
Medium	10	54.45	3.668	0.1889	2.00	0.27
1 <sup>0</sup> treated waste H <sub>2</sub> O	10	53.1	3.736	0.1857	1.87	0.26
2 <sup>0</sup> treated waste H <sub>2</sub> O	10	55.0	3.659	0.1894	2.17	0.27
Sample 3						
Temp : 35-45 °C						
Tap water	10	11.67	22.4	0.0309	0.74	0.42
Medium	10	12.39	16.18	0.0428	0.69	0.41
1 <sup>0</sup> treated waste H <sub>2</sub> O	10	10.77	46.72	0.0148	0.62	0.48
2 <sup>0</sup> treated waste H <sub>2</sub> O	10	10.87	41.56	0.0166	0.70	0.44

**Graph 1:**-Comparison of RGR of *Azolla* at different temperatures

**Graph 2:-**Comparison of DT of Azolla at different temperatures

The experiment showed that the ideal temperature for growth of *Azolla* was found to range from 20 to 35<sup>0</sup>C. The highest growth rate with the least DT was shown by *Azolla* fronds grown at a temperature range of 20-35<sup>0</sup>C.

### Objective 2:-Physico-Chemical Parameter Analysis

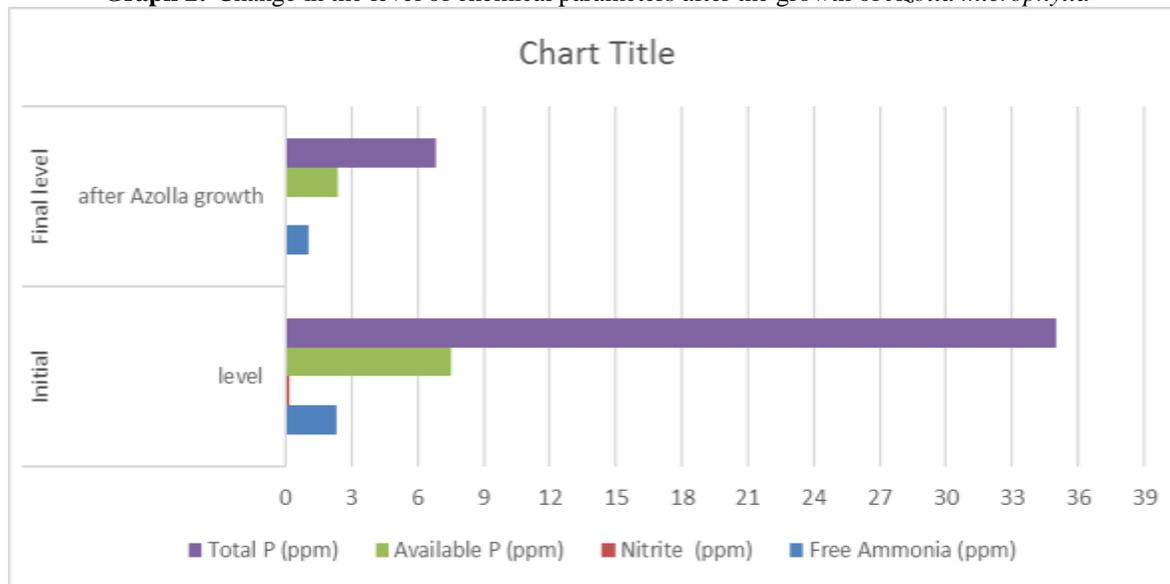

The water samples collected were analyzed for physical parameters like color and pH, and chemical parameters like Total Organic Carbon, Organic Matter, Total P, Available P, Nitrite and Ammonia. The pH of the samples was in range of 7.5 to 8.9 and growth of *Azolla* has caused a slight increase in the pH. The color of the primary treated wastewater was brown which had turned colorless after growth of *Azolla*. However, the secondary treated wastewater was colorless initially and finally.

Growth of *Azolla* was able to bring down the TOC, nitrite, total and available phosphorus and ammonia levels (Table 2). Growth of *Azolla* had brought down the total organic carbon level to 50 per cent for secondary treated water. Organic matter was 33 per cent. The Biological Oxygen Demand of both primary and secondary treated wastewater was very much within limits. Total P value has shown a reduction of 80 per cent in secondary treated effluent. The reduction in the phosphorous values can be attributed to the fact that phosphorous is the limiting nutrient for growth of *Azolla*. The ammonia levels of secondary treated wastewater had shown a reduction of 54.8 per cent. This shows that ammonium ions did not always inhibit growth and nitrogen fixation of *Azolla* (Kitoh et al, 1993). Nitrite content of the wastewater was also analyzed. Nitrite was found to be higher in secondary treated wastewater. This may be supported by the nitrification process of conversion of ammonia to nitrite, as ammonia content of the secondary treated wastewater was low. There was 71.4 per cent removal in nitrite content after *Azolla* growth. This may be attributed to the micro flora present in the wastewater and in association with *Azolla microphylla*.

**Table 2:-**Chemical parameters before and after the growth of *Azolla* in secondary treated sewage water

Chemical Characteristics of the municipal water sample	Initial level	Final level after the growth of <i>Azolla microphylla</i>	Percentage Removal of nutrients after the growth of <i>Azolla</i>
Free Ammonia (ppm)	2.3	1.04	54.78
Nitrite (ppm)	0.161	0.046	71.42
Available P (ppm)	7.5	2.35	68.66
Total P (ppm)	35	6.8	80.57
Total Organic C (%)	0.10	0.05	50.0
Organic matter (%)	0.6	0.4	33.3
BOD (mg/L)	230	19	91.73
COD (mg/L)	676	85	87.42

**Graph 2:-**Change in the level of chemical parameters after the growth of *Azolla microphylla*

**Discussion:-**

The ability of *Azolla* to carry out bioremediation of wastewater was analyzed and the study has shown good results of removal of total organic carbon, phosphorous and nitrogen and proves to be efficient in removal of ammonia. The presence of nitrogen and phosphorus leads to the growth of algae (eutrophication) which consumes oxygen of water bodies and destroying natural flora and fauna leading to their death. *Azolla* growths which were found to be at peak at 20-35<sup>0</sup>C did not allow the growth of algae while the uninoculated controls maintained had algal growth in them. At 35-45<sup>0</sup>C when growth and multiplication of *Azolla* was negligible due to unfavorable temperature, there was growth of algae in both primary and secondary treated sewage water. *Azolla* uses a low cost Espinase and Watanabe medium with no nitrogen added to it (Dawar and Singh, 2002; Yadav et al., 2014). This is due to the presence of *Anabaena Azollae* which is in association with *Azolla*. It fixes atmospheric nitrogen for *Azolla* (Pabby et al., 2003; Arora et al., 2003). The biomass analysis shows that the greater nitrogen, phosphorus, potassium and organic content could favor the use of *Azolla* as a biofertilizer, especially when it grown in domestic wastewaters, and also when it is harvested from natural environments. Since *Azolla* can accumulate phosphorus, the concentration of this element in the plant was as higher as the growth medium was rich on phosphate. The used *Azolla* biomass can be applied as green manure after testing for heavy metal presence. If the presence of heavy metal is detected then it should be dried and extracted for heavy metal extraction or incinerated to prevent further recycling in the environment (Sood et al., 2012). Further the potential of *Azolla* can be made use of in developing operational constructed wetlands. Constructed wetlands have been set up with rooted plants like typha, phragmites, canna but the option of using *Azolla* in combination with these rooted plants will enhance the removal of nutrients and heavy metals with less time.

**Conclusion:-**

Improvement in water quality, soil and removal of pollution with the added advantage of dual cropping proves *Azolla* to be a promising plant for maintaining a sustainable environment. Policy makers and the scientific community are equally challenged to seek solutions to mitigate the environmental issues of ecosystem services loss including water, biomass and global climate regulation. *Azolla* can prove to be a promising organism for these problems. *Azolla* is thus an ideal plant for polishing of wastewater and can be efficiently used in constructed wetland.
