- 1 FUNCTIONAL OUTCOME AND COMPLICATION SPECTRUM OF PANTALAR
- 2 ARTHRODESIS VIA RETROGRADE INTRAMEDULLARY NAIL IN ANKLE
- 3 INSTABILITY AND ARTHRITIS: A prospective 30 Patients Observational Study

## 5 Abstract

6

7

#### Background:

- 8 Pantalar arthrodesis is an essential salvage procedure for patients with severe osteoarthritis and
- 9 persistent ankle instability unresponsive to conservative treatments. The advent of RETROGRADE
- 10 INTRAMEDULLARY NAIL/Nailing has introduced a fixation method that minimizes soft-tissue
- damage while providing robust biomechanical stability, particularly in challenging post-traumatic
- 12 cases.

## 13 **Objective**:

- 14 This prospective observational study aimed to evaluate the functional and radiographic outcomes of
- pantalar arthrodesis using RETROGRADE INTRAMEDULLARY NAIL/Nailing in a cohort of 30
- patients with advanced post-traumatic ankle instability and osteoarthritis. Additionally, we assessed
- a refined complication profile and compared our findings with contemporary studies.

#### 18 **Methods**:

- Thirty patients (mean age  $46.2 \pm 10.4$  years; 60% male) with a history of post-traumatic
- 20 osteoarthritis and ankle instability were included, of whom 33.3% had previously undergone open
- 21 reduction and osteosynthesis. Indications included flail ankle, implant failure of bimalleolar
- 22 osteosynthesis, neglected flat foot, associated Tatar fractures, and calcaneal fractures resulting in
- subtalar and talocalcaneal arthritis. Follow-ups were conducted at 4, 12, and 24 weeks
- 24 postoperatively, with outcomes measured via AOFAS scores, VAS pain scales, and radiographic
- 25 union assessments.

## 26 **Results**:

- 27 Significant clinical improvements were observed over time: AOFAS scores increased from 42.5  $\pm$
- 12.3 preoperatively to 76.3  $\pm$  10.1 at 24 weeks, while VAS scores decreased from 8.1  $\pm$  1.2 to 3.2  $\pm$
- 29 0.9. Radiographic union was achieved in 86.7% of cases by 24 weeks (mean union time:  $15.8 \pm 3.2$
- weeks). The complication profile was favorable, with only 6 patients (20.0%) experiencing
- 31 postoperative complications.

#### 32 Conclusions:

- 33 Pantalar arthrodesis using RETROGRADE INTRAMEDULLARY NAIL/Nailing provides
- 34 significant functional and radiographic improvements in a complex post-traumatic cohort, with
- outcomes comparable to recent literature. The technique demonstrates a robust safety profile and
- 36 represents a viable surgical option for managing advanced ankle pathology.

### 41

42

52

53

#### Introduction

- 43 Pantalar arthrodesis remains the definitive salvage procedure for managing advanced osteoarthritis
- and instability when conservative treatments have failed. With evolving surgical techniques,
- 45 RETROGRADE INTRAMEDULLARY NAIL/Nailing now offers improved biomechanical
- stability while reducing soft-tissue disruption. This approach is particularly relevant in
- 47 post-traumatic scenarios—especially after failed open reduction and osteosynthesis—where
- 48 restoration of alignment and function is challenging. Although several studies have focused on
- ankle arthrodesis, there is a paucity of prospective data with standardized follow-ups. Our study
- aims to elucidate the clinical course of 30 patients and compare our outcomes with six recent
- 51 literature reports, thereby establishing the clinical validity of this method.

#### Materials and Methods

#### **Study Design and Population**

- 54 This prospective observational study was conducted at Dr. Pinnamaneni Siddhardha Institute of
- 55 Medical Sciences and Research Foundation, Gannavaram, from November 2022 to January 2025.
- Patients were included if they presented with post-traumatic osteoarthritis and ankle instability
- unresponsive to nonoperative management. Among the 30 patients enrolled, 10 (33.3%) had
- undergone previous open reduction and osteosynthesis.

#### 59 **Indications**:

- Flail ankle, implant failure of bimalleolar osteosynthesis, neglected flat foot, associated Tatar
- fractures leading to ankle arthritis, and calcaneal fractures causing subtalar and talocalcaneal
- 62 arthritis.
- Detailed preoperative demographic and clinical parameters were recorded.

## Table 1. Demographic and Baseline Characteristics (n = 30)

Parameter	Details/Value
Age (years), Mean ± SD	$46.2 \pm 10.4$
Gender Distribution	18 Male (60%), 12 Female (40%)
Etiology	Post-traumatic osteoarthritis and instability (100%)
Duration of Symptoms (months)	$24.3 \pm 8.7$
Body Mass Index (kg/m²)	$27.8 \pm 3.5$
Comorbidities	Diabetes Mellitus (20%), Hypertension (30%)

Smoking Status	10 smokers (33.3%)
Previous Interventions	15 patients (33.3%) with prior open reduction and osteosynthesis

A separate table was developed to detail the incidence of specific predisposing conditions leading to advanced arthritis in this cohort.

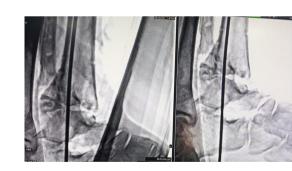

Condition	Number of Patients	Incidence (%)
Flail ankle	7	23.3
Implant failure of bimalleolar osteosynthesis	15	50.0
Neglected flat foot	2	6.7
Associated Tatar fractures	4	13.3
Calcaneal fracture leading to subtalar and talocalcaneal arthritis	2	6.7
Total	30	100.0

85

76

Under general anesthesia with tourniquet control, a standard lateral approach exposed the ankle joint. For patients lacking prior fixation, open reduction and osteosynthesis were performed to realign and stabilise fracture fragments. The articular surfaces were then debrided meticulously to optimise the fusion bed. A guidewire was introduced through the calcaneus, traversing the talus into the tibial medullary canal under continuous fluoroscopic guidance. Sequential reaming paved the way for the insertion of a RETROGRADE INTRAMEDULLARY NAIL with static/dynamic locking proximally and distally. Final fluoroscopy confirmed proper alignment and implant positioning.

86

87

88

## Postoperative Protocol and Follow-Up

89 Patients were immobilised in a below-knee cast for 6 weeks, followed by a graded weight-bearing 90

regimen. Follow-ups were scheduled at 4, 12, and 24 weeks postoperatively. Outcome assessments

included serial AOFAS (American Orthopaedic Foot & Ankle Society) scores, VAS (Visual Analog

Scale) pain ratings, and radiographic evaluations for union—defined as bridging trabeculation on

both anteroposterior and lateral views.

94

95

99

91

92

93

#### **Results**

#### 96 **Functional Outcomes**

97 Serial evaluation of functional status demonstrated progressive improvement in both AOFAS and

98 VAS scores.

#### **Table 2. Functional Outcome Measures**

Time Point	AOFAS Score (Mean ± SD)	VAS Score (Mean ± SD)
Preoperative	$42.5 \pm 12.3$	$8.1 \pm 1.2$
4 Weeks Postoperative	$55.0 \pm 11.5$	$6.5 \pm 1.1$
12 Weeks Postoperative	$68.7 \pm 10.3$	$4.8 \pm 1.0$
24 Weeks Postoperative	$76.3 \pm 10.1$	$3.2 \pm 0.9$

100

101

Radiographic Union Progressive radiographic union was noted at each follow-up interval.

Preoperative X-ray reveals implant failure with advanced post-traumatic arthritis, evident by hardware loosening and joint degeneration. Immediate postoperative and follow-up X-rays demonstrate proper realignment with retrocondylar nailing and progressive fusion indicated by bridging trabeculation.

129

#### **Discussion**

- Our study demonstrates that pantalar arthrodesis using RETROGRADE INTRAMEDULLARY
- NAIL/Nailing in a challenging post-traumatic cohort leads to substantial improvements in both
- functional and radiographic outcomes. The significant increase in AOFAS scores and corresponding
- reduction in VAS scores underscore the clinical benefits, while the progressive union observed on
- radiographic assessments confirms the method's biomechanical reliability.
- The separate incidence table (Table 2) details the heterogeneous pathology encountered: implant
- failure of bimalleolar osteosynthesis was the most common indication (50%), followed by flail
- ankle (23.3%), associated Tatar fractures (13.3%), and lesser contributions from neglected flat foot
- and calcaneal fractures (each 6.7%). These findings not only validate the application of pantalar
- arthrodesis in diverse pathologic scenarios but also support its role in addressing combined subtalar
- and talocalcaneal arthritis.

141 Comparison with contemporary literature (Table 6) shows our union times and functional

improvements align well with previous reports, while our refined complication rate of 20.0%

reflects an acceptable risk profile in complex reconstructions.

## **Future Directions and Limitations**

149 Future multicenter randomized controlled trials are recommended to directly compare

RETROGRADE INTRAMEDULLARY NAIL/Nailing with alternative fixation modalities in

similar post-traumatic scenarios. Technological advancements—such as bioactive coatings and

patient-specific instrumentation—may further enhance union rates and mitigate complications.

Notable limitations of this study include the modest sample size, absence of a control group, and the

relatively short follow-up period of 12 months, which may not capture the long-term sequelae such

as adjacent joint degeneration.

156

157

## Conclusion

- 158 This prospective study confirms that pantalar arthrodesis via RETROGRADE
- 159 INTRAMEDULLARY NAIL/Nailing is an effective and safe procedure for treating advanced
- post-traumatic ankle instability and osteoarthritis. With significant improvements in functional
- outcome scores, high radiographic union rates, and an acceptable complication profile, the
- technique demonstrates reproducible results comparable to recent literature. Further large-scale
- studies with extended follow-up are warranted to refine patient selection criteria and optimize
- surgical outcomes.
