### Reviewer's Comment for Publication.

The case report titled "*A Challenging Case of Hemorrhagic Stroke in a Patient with Fusiform Aneurysm with Partial Thrombosis*" presents a clinically significant and complex scenario involving the coexistence of two pathologies with conflicting therapeutic approaches. The abstract provides a clear overview of the clinical dilemma posed by the simultaneous presence of cerebellar hemorrhage and a partially thrombosed fusiform aortic aneurysm in a hypertensive patient.

The background emphasizes the rarity and growing clinical relevance of such cases in the context of rising hypertension prevalence. The case presentation is detailed and coherent, outlining the patient's history of long-standing hypertension, clinical symptoms, imaging findings, and the incidental yet critical discovery of the aortic aneurysm with mural thrombus. The decision-making challenge regarding anticoagulation in the presence of hemorrhage is well-articulated and captures the nuanced balance required in managing such opposing pathophysiological conditions.

The conclusion succinctly reiterates the uniqueness of the case and the importance of clinical vigilance in the simultaneous management of hemorrhagic and thrombotic events. The discussion of cerebellar hemorrhage and its pathophysiology in the introduction provides an appropriate background, situating the case within a broader clinical context.

Overall, the case report is compelling, medically informative, and highlights the practical challenges faced by clinicians in handling dual pathology. It serves as a valuable addition to medical literature on stroke management and complex cardiovascular-neurological overlap cases.
