- 1 Comparative assessment of BMP-9 levels and clinical implant parameters in
- 2 immediately restored implants using bone compaction drilling versus conventional
- 3 drilling: a randomized controlled study.
- 4 ABSTRACT

- 5 Background-This study aimed to compare the effects of bone compaction drilling and
- 6 conventional drilling techniques on bone marker BMP-9 and clinical implant parameters.

- Materials and Methods: Forty-two participants were randomized into two groups (n = 21
- 8 each): OD and CD. Randomization was computer-generated with allocation concealment,
- 9 and both participants and outcome assessors were blinded. Over a 6-month follow-up,
- peri-implant crevicular fluid (PICF) levels of bone morphogenetic protein-9 (BMP-9),
- implant stability, and crestal bone loss were evaluated.
- Results: At 2 weeks, the CD group exhibited significantly higher BMP-9 levels (177.67  $\pm$
- 13 8.24 pg/mL) than the OD group (150.43  $\pm$  4.96 pg/mL; p < 0.05). By 16 weeks, the OD
- group showed greater BMP-9 expression (440.90  $\pm$  33.57 pg/mL vs. 423.62  $\pm$  15.58

- pg/mL). Implant stability was consistently higher in the OD group at all time points, with
- 16 ISQ values initially declining at 2 weeks and increasing thereafter in both groups. The OD
- group also demonstrated significantly less crestal bone loss at each follow-up interval (p
- 18 <.05).

#### 19 Conclusion:

- 20 Bone compaction drillingor osseodensificationusing Densah burs demonstrated enhanced
- secondary healing, as indicated by increased BMP-9 levels, along with improved implant
- 22 stability and reduced crestal bone loss compared to conventional drilling. These findings
- 23 indicate a potential biomechanical advantage for implant placement.

### INTRODUCTION

- 27 Dental implants have completely transformed the realm of oral rehabilitation with a well-
- documented success rate typically ranging between 90% 95% after 10 years of follow-
- 29 ups. 1,2 However in the maxillary arch, there's often a deficiency in both the quality and
- quantity of bone, because of which achieving successful osseointegration of implants is
- 31 particularly challenging. Insufficient bone surrounding implants may adversely affect
- implant stability, percentage of bone-to-implant contact (BIC) and bone volume (BV),
- which consequently delays osseointegration.<sup>3</sup>
- In the past, undersizing the osteotomy, osteotome technique by Summer's and implant
- 35 site preparation using peizosurgery<sup>6</sup> have been introduced to improve osseointegration in
- low bone density areas. However major drawbacks like increased mechanical strain on the
- 37 bone leading to bone compression and ischemia, increased marginal bone loss and risk of
- 38 overheating associated with ultrasonic devices reduced the clinical implications of these
- techniques. 6,7,8 Also use of wider, longer implants with a reverse buttress, larger thread
- depth, narrow pitch and a self-tapping design were reported to be beneficial in
- 41 compromised bone sites.<sup>9</sup>
- 42 Huwais in 2013<sup>10</sup> developed an innovative osteotomy preparation method known as
- osseodensification (OD). This bone compaction drilling technique sparked a significant
- change in the methods used for implant site preparation, being a non-subtractive drilling
- 45 technique. Osseodensification technique is indicated where there is insufficient quantity or
- quality of bone. Relying on the elastic and plastic properties of bone, the

69 MATERIALS AND METHODS

70 A two yearstudy was carried out in a tertiary hospital setting. Ethical approval (XIV-71 PGTSC-IIA/PII) was obtained and registration in the Clinical Trial Registry of India 72 (ICMR-NIMS) (CTRI/2023/03/050409) was done prior to the commencement of the study. The study followed a randomized controlled design (computer-generated random numbers) 73 with participants and outcome assessor blinding following the CONSORT (Consolidated 74 Standards of Reporting Trials) guidelines. 19 Allocation of treatment was concealed using 75 opaque sealed envelope. Sample size of 21 participants in each group was calculated based 76 77 on the minimum difference  $d = max(\sigma 1, \sigma 2)$ , considered to be clinically significant. Type I error  $\alpha = 5\%$  corresponding to 95% confidence level, Type II error  $\beta = 10\%$  for detecting 78 results with 90% power of study. 17 79 Participants visiting prosthodontics clinic for rehabilitation of a single edentulous space in 80 the maxillary arch that could be restored with an implant supported single unit crown were 81 screened as per predetermined inclusion and exclusion criteria (Figure 1). Participants 82 aged 18-60 years of both genders, capable of comprehending and signing an informed 83 consent, with a bounded edentulous space in the maxillary arch post-extraction for at least 84 3 months were included. Keratinized tissue >2 mm from mid crest to mucogingival 85 junction, simplified oral hygiene index of 0-3 indicating good to fair oral hygiene and 86 adequate bone for optimal implant placement and a safe distance (>2 mm) from vital 87 88 tissues and an opposing dentition with a stable occlusion were assessed and included in the study. 89 Participants with history of systemic conditions or under medications, presence of any 90 local risk factor, history of treated periodontitis, smoking, any parafunctional habits, 91 pregnant or lactating women were excluded. Also participants fulfilling any criteria either 92 93 group 1 or 2 according to second ITI (International Team of Oral Implantology) Consensus 📶 turnitin

119	1000 rpm for 10 minutes and stored at -80°C. While PICF volume was not measured
120	directly, standardization was ensured by consistent sampling time and PBS dilution. BMP-
121	9 levels were quantified using sandwich ELISA technique (E0051Hu, Bioassay
122	Technology Laboratory, Zhejiang, China) and expressed in picogram/millilitre.
123	Primary implant stability was assessed immediately after implant placement. Smart Peg
124	(MIS Implants Technologies Ltd, Israel) specific to the implant system and the restorative
125	platform diameter was utilized and subsequently resonance frequency analysis (RFA) was
126	conducted using Osstell (Integration Diagnostics, Savedalen, Sweden)). Average of three
127	readings was recorded in terms of implant stability quotient (ISQ). Secondary stability was
128	recorded in similar way in terms of ISQ values assessed at 2 weeks, 8 weeks and 16 weeks.
129	(Figure 5B).
130	Standardized periapical radiographs were captured using the long-cone paralleling
131	technique, with individualized sensor holders employed for consistent and reproducible
132	positioning. The acquired images were analysed using ImageJ software (National Institutes
133	of Health, Bethesda, MD, USA). Dimensional calibration of the images was performed
134	using the known length of the inserted implant to correct for any magnification errors.
135	Crestal bone loss was measured by subtracting the baseline measurements recorded at the
136	time of provisional prosthesis delivery frommeasurements taken at 2 weeks, 8 weeks, 16
137	weeks, and 6 months postoperatively (Figure 5C). Radiographic analysis was conducted
138	independently by two calibrated investigators. To assess intra- and inter-examiner
139	reliability, 20% of the radiographs were randomly selected and re-evaluated after a two-
140	week interval. Intra-class correlation coefficients (ICCs) were calculated, and values above
141	0.85 were considered acceptable, indicating high reliability. To determine the method
142	error, duplicate measurements were analysed using Dahlberg's formula, and the standard
143	error of measurement (SEM) was calculated. This ensured that any reported differences in

- bone loss between groups exceeded the magnitude of measurement error, thereby
- supporting the validity of the statistical findings.
- Sample size was calculated based on the variation in BMP-9 levels among the study
  - groups, using the appropriate formula which is

148 
$$n = k \frac{\left(z_{\alpha} + z_{\beta}\right)^{2} \left(\sigma_{1}^{2} + \sigma_{2}^{2}\right)}{d^{2}}$$

- Where n = number of samples to be collected
- $\sigma 1 = 300$ , The SD of BMP-9 in first group with reduced torque,  $\sigma 2 = 250$ , The SD of
- 13 151 BMP-9 in second group with conventional torque.<sup>33</sup> The data were analysed with a
  - statistical software package (IBM SPSS Statistics, v26.0; IBM Corp) ( $\alpha = .05$ ).<sup>22</sup> Unpaired t
  - test, repeated measures ANOVA followed by Bonferroni post hoc analysis and Pearson's
  - 154 correlation were the statistical tools used.

### 156 **RESULTS**

- The OD group had notably lower levels of BMP-9 after 2 weeks compared to the CD
- group (OD group: 150.43±4.96 and CD group: 177.67±8.24) which was statistically
- significant(P < 0.05). However, the levels of BMP-9 were higher at 8 weeks (OD group:
- 274.19  $\pm$ 12.16 and CD group: 267.24 $\pm$ 14.50) and 16 weeks (OD group: 440.90 $\pm$ 33.57 and
- 161 CD group: 423.62±15.58) in the osseodensification group with the difference being
- statistically significant at 16-week(P < 0.05). There was a consistent upward trend in BMP-
- 9 levels from the 2nd week to the 16th week in both the groups indicating increased
- formation of bone during this period. (Table 1)
- The mean ISQ values at baseline (OD group: 75.19±4.92 and CD group: 64.90±6.80), at 2
- weeks (OD group: 69.24±7.74 and CD group: 61.43±8.26), at 8 weeks (OD group:
- 167 72.76±5.12 and CD group: 62.95±8.40) and at 16 weeks (OD group: 74.62±4.57 and CD

19	168	group: 64.57±4.17) indicated that the implant stability of the OD group was more than the
	169	CD group which was statistically significant ( $P < 0.05$ ) at every time point. There was a
	170	decrease in the ISQ values at 2 weeks when compared to the baseline and subsequently
	171	showed a gradual increase in both the groups. (Table 2)
33	172	There was evidence of significant difference $(P<0.05)$ in the crestal bone loss of both the
3	173	OD and CD groups at all the time intervals. The mean values of crestal bone loss in mm at
	174	2 weeks (OD group: $0.07\pm0.01$ and CD group: $0.10\pm0.03$ ), at 8 weeks (OD group:
	175	0.24±0.03 and CD group: 0.29±0.05), at 16 weeks (OD group: 0.37±0.05 and CD group:
	176	0.45±0.07) and at 6 months (OD group: 0.58±0.09 and CD group: 0.67±0.08) indicated
<b>2</b> 6	177	that the crestal bone loss of the CD group was significantly more than the OD group.
	178	(Table 3)
	179	Pearson's correlation analysis showed that there was a significant $(P<0.05)$ correlation
	180	between BMP-9 and implant stability in the OD group and between BMP-9 and crestal
	181	bone loss in the both the OD and CD group (Supplementary Table 1 and2)
	182	
	183	DISCUSSION
	184	Over the past two decades, significant advancements in implantology have positioned
	185	endosseous implants as the preferred method for replacing missing teeth. Despite their
	186	widespread success, implant failures do occur, with rates reaching 8.16% and 4.93% in the
5	187	maxillary and mandibular arch respectively. <sup>22</sup> Thiebotet al <sup>23</sup> noted that in most cases of
31	188	implant failures, the bone involved was classified as type III or IV. Ko et al <sup>24</sup> showed that
	189	the cortical bone thickness is least in the anterior and posterior maxilla, elucidating why

83% of the failures identified in Thiebot et al 's study occurred in the maxilla, as also

observed in Kern et al's5-year follow-up investigation.<sup>25</sup>

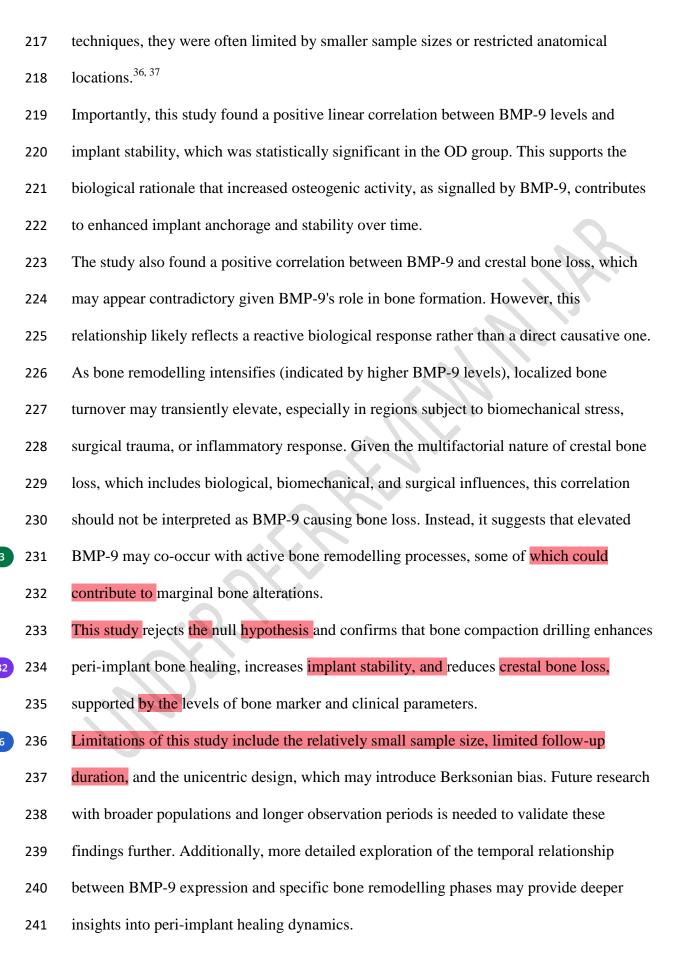

190

📶 turnitin

The osseodensification technique, introduced by Huwaisin 2013<sup>10</sup>utilizes specially 192 designed Densah burs to preserve and compact bone rather than removing it. This method 193 194 promotes dense autografted bone formation around the implant, improving bone-implant contact and increasing insertion torque, thereby ensuring primary implant stability. 11 195 The demographic analysis confirmed no significant influence of age or gender between the 196 groups, ensuring homogeneity. The central biological marker evaluated in this study was 197 bone morphogenetic protein-9. BMP-9 plays a pivotal role in osteoblast differentiation and 198 bone tissue formation by activating the SMAD-dependent signalling pathway. <sup>26</sup>Studies by 199 Nieet al<sup>27</sup>, Kawecki F<sup>28</sup>, Haimov H<sup>29</sup> and others have enumerated the recent applications of 200 BMP-9 ranging from alveolar bone healing to coatings on titanium implants. 201 202 BMP-9 levels increased progressively across all time points in both groups, with significantly higher levels observed in the OD group at the 8- and 16-week follow-ups. 203 These findings align with the known osteoinductive properties of BMP-9, which peak 204 during thelate stages of bone remodelling.<sup>30</sup> The lower levels observed in the OD group at 205 2 weeks may reflect the delayed inflammatory and resorptive phase due to early bone 206 compaction. 14 By 8 and 16 weeks, healing chambers created by OD likely served as active 207 sites for osteogenesis, accounting for elevated BMP-9 expression. 31,32 208 Implant stability values both primary and secondary were significantly higher in the OD 209 210 group compared to the CD group. These results which are in alignment withother animal and human studies, <sup>13,15,33,34, 35</sup> reinstate that OD promotes a biomechanical environment 211 212 conducive to immediate and long-term implant success. 213 Additionally, crestal bone loss was significantly lower in the OD group at all follow-ups. 214 This can be attributed to increased bone volume, higher bone density, and reduced micromovement due to superior primary stability. Although some previous studies have 215 reported no statistically significant difference in crestal bone loss between drilling 216

#### **CONCLUSION**

Within the limitations of the present study, it can be concluded that the bone compaction drilling technique demonstrated a superior biological response compared to conventional drilling, as evidenced by elevated BMP-9 levels. Additionally, clinical parameters, including improved implant stability and reduced crestal bone loss, further support the efficacy of osseodensification as a favourable technique for implant placement.

373

## Table 1. Comparison of levels of BMP-9 in OD and CD groups

	Group	N	Mean	Std.	Std. Error	p-value
BMP Levels						
			(pg/ml)	Deviation	Mean	
2 wk	OD group	21	150.43	4.96	1.083	0.000 <sup>a</sup>
2 WK	CD group	21	177.67	8.24	1.798	
8 wk	OD group	21	274.19	12.16	2.653	0.100
	CD group	21	267.24	14.50	3.164	
16 wk	OD group	21	440.90	33.57	7.326	0.039 <sup>a</sup>
	CD group	21	423.62	15.58	3.400	

- Values are presented as mean±standard deviation 374
- CD- conventional drilling, OD- osseodensification drilling 375
- <sup>a)</sup>Statistically significant difference 376

### Table 2. Comparison of implant stability in OD and CD groups

turnitin turnitin

385

Implant	Group	N	Mean	Std.	Std.	p-value
Stability			(ISQ)	Deviation	Error	
					Mean	
Baseline	OD group	21	75.19	4.92	1.074	$0.000^{a}$
	CD group	21	64.90	6.80	1.484	R
2 weeks	OD group	21	69.24	7.74	1.688	$0.003^{a}$
	CD group	21	61.43	8.26	1.802	/3
8 weeks	OD group	21	72.76	5.12	1.116	$0.000^{a}$
	CD group	21	62.95	8.40	1.834	
16 weeks	OD group	21	74.62	4.57	0.996	$0.000^{a}$
	CD group	21	64.57	4.17	0.909	

Values are presented as mean±standard deviation

CD- conventional drilling, OD- osseodensification drilling

## Table 3. Comparison of crestal bone loss in OD and CD groups.

Crestal	Group	N	Mean	Std.	Std. Error	p-value
bone loss			(mm)	Deviation	Mean	
2 weeks	OD group	21	0.071	0.011	0.0025	0.000 <sup>a</sup>
	CD group	21	0.104	0.026	0.0057	
8 weeks	OD group	21	0.244	0.028	0.0060	0.001 <sup>a</sup>
	CD group	21	0.287	0.049	0.0107	
16 weeks	OD group	21	0.367	0.055	0.0120	0.000a
	CD group	21	0.469	0.070	0.0152	
6months	OD group	21	0.584	0.094	0.0205	0.002 <sup>a</sup>
	CD group	21	0.675	0.080	0.0174	

396 Values are presented as mean±standard deviation

397 CD- conventional drilling, OD- osseodensification drilling

398 <sup>a)</sup>Statistically significant difference
