#### **Introduction:-**

The reaction proceeds efficiently in high yields at ambient temperature within a few minutes. Various 1,3-dicarbonyl compounds including alkyl acetoacetates, acetylacetone, benzoylacetone,  $\omega$ -benzoylacetophenone, acetoacetamides and benzoylacetanilides give the corresponding substituted quinolines without any side products. In general the reaction is very clean, rapid and efficient and involves a simple work-up procedure. Unlike previous methods, the present protocol does not require high temperature to produce quinoline derivatives.

Friedlander synthesis is an acid or base catalyzed condensation followed by a cyclodehydration between an aromatic 2-aminoaldehyde or ketone with the carbonyl compound containing a reactive  $\alpha$ -methylene group. 2-Aminobenzaldehyde condense readily with active methylene compounds in the presence of base1 and acid2 catalysts to give quinolines. However, some of these methods suffer from disadvantages such as long reaction times, lower yields and requirement of severe conditions. Therefore, the development of new methods with greater efficacy, straightforward procedures and better yields still is desirable.

Interest in solvent-free reactions has increased in recent years, though reactions in solution are much more common. This is due to the fact that, in many cases, ground state organic reactions occur more effectively and selectively than the solution reactions. Furthermore, the solvent-free reaction has many advantages such as reduced pollution, low costs and simplicity in process and handling.

In view of this, herein we report the CeCl3. 7H2O catalyzed Friedlander condensation under solvent-free grinding conditions at RT. The synthetic route is presented in Scheme I.

#### Scheme I

#### **Experimental Section**

A mixture of 2-aminobenzaldehyde 1 (0.01 mole), active methylene compound 2 (0.01 mole) and  $CeCl_3.7H_2O$  (0.01 mole) was ground by pestle and mortar at room temperature for the period indicated in Table II. On completion of the reaction as monitored by TLC, the reaction mixture was treated with cold water. The solid separated was filtered, washed with water and recrystallized from appropriate solvent to furnish 3 (Table II). The aqueous layer containing the catalyst could be evaporated under reduced pressure to give a white solid. The catalyst was recovered and reused in subsequent reactions, three times without losing any significant activity. The newly synthesized compounds were further confirmed by IR and <sup>1</sup>HNMR analysis data.

## **Results And Discussion:-**

Spectral and analytical physical data were described below tables I & II.

Table II:- Yield %, Reaction period and Physical data of quinolines 3.

### Conclusion;-

We have demonstrated a simple and efficient procedure for the synthesis of quinolines by employing  $CeCl_3.7H_2O$  as a reusable catalyst. The salient features of this method include operational simplicity, improved reaction rates, high yields of products and avoidance of the use of hazardous acids or bases.
